

## Beam Tilt & TFC: Which z value for correction?

1. **Standing plan:** correct using **barrel of innermost hit**
2. Alternate: also use barrel-crossing pattern

Compare means of

$$\delta z = \text{track} - \text{barrel center}$$

for both 1 and 2.

ZH → ννbb

no beam tilt

6 for barrels

3 summary  
no tilt, expect  
 $r = 0$   
 $\phi = \text{random}$

# Tilt sample

.  $x, y = 3 \text{ mm/cm}$

so expect

$m_r = 4.24$

$\text{mm/cm}$

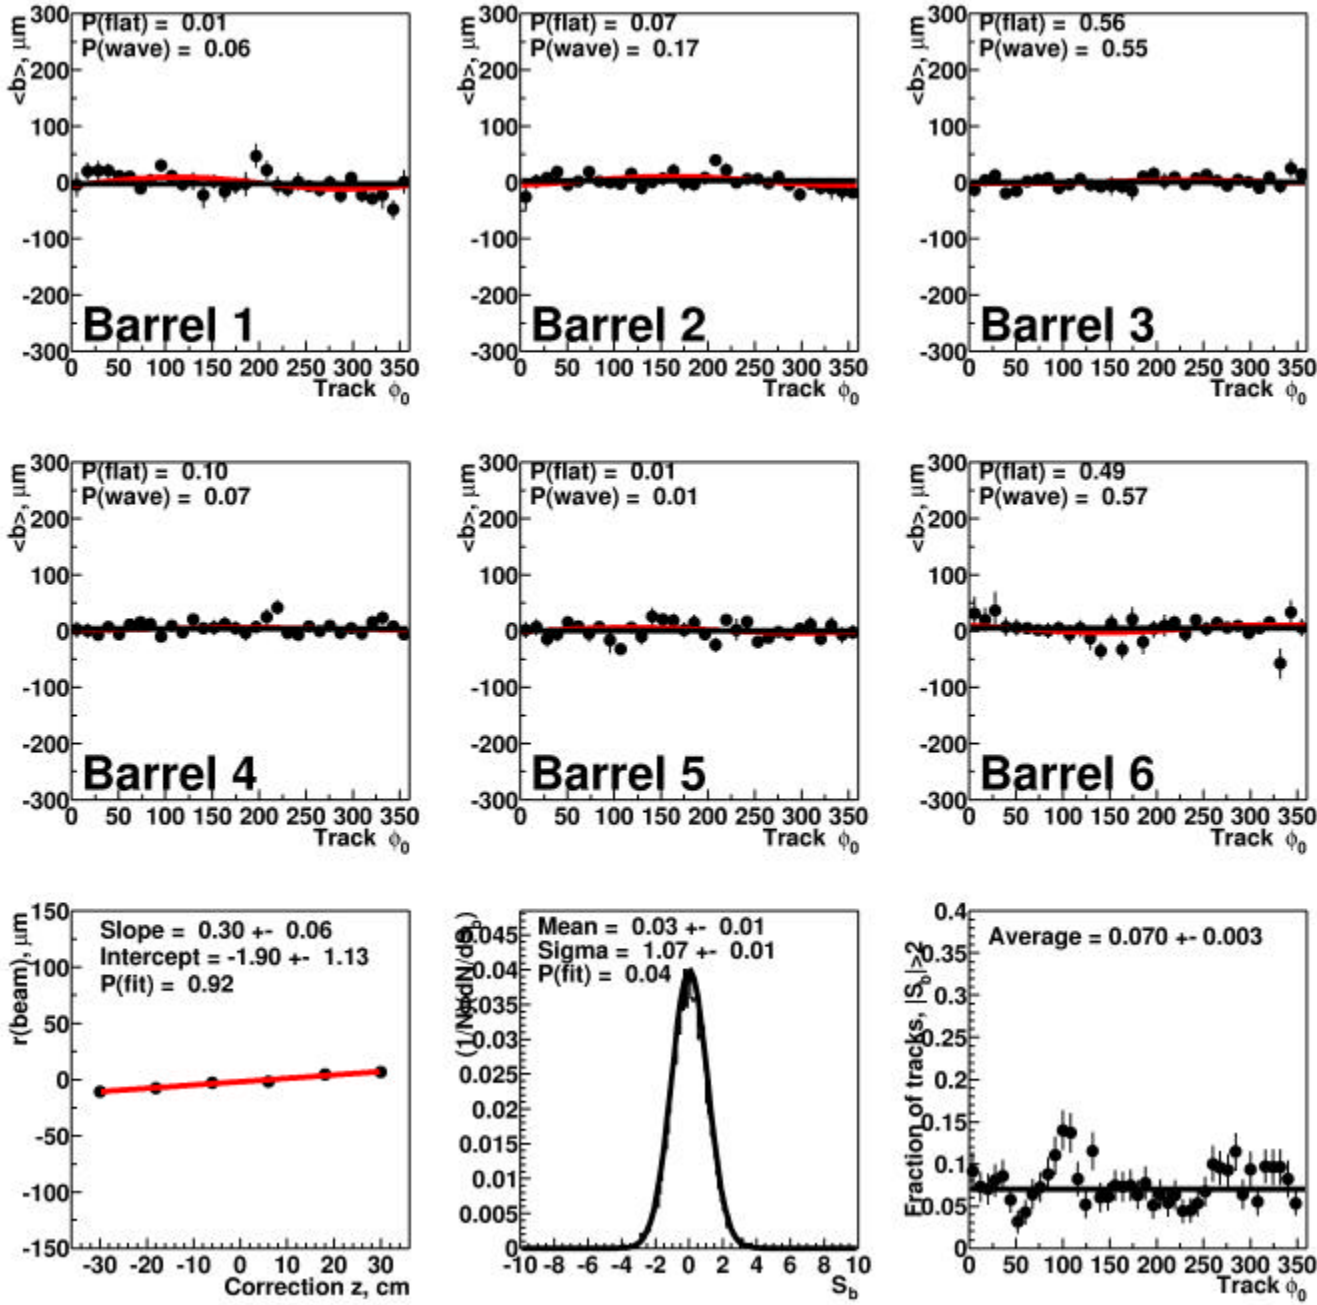

Tilt sample, again

after applying  
barrel correction

expect  
 $m_r = 0 \text{ mm/cm}$   
 $\phi = \text{random}$

find,  
 $m$  consistent w/C  
Slightly better b

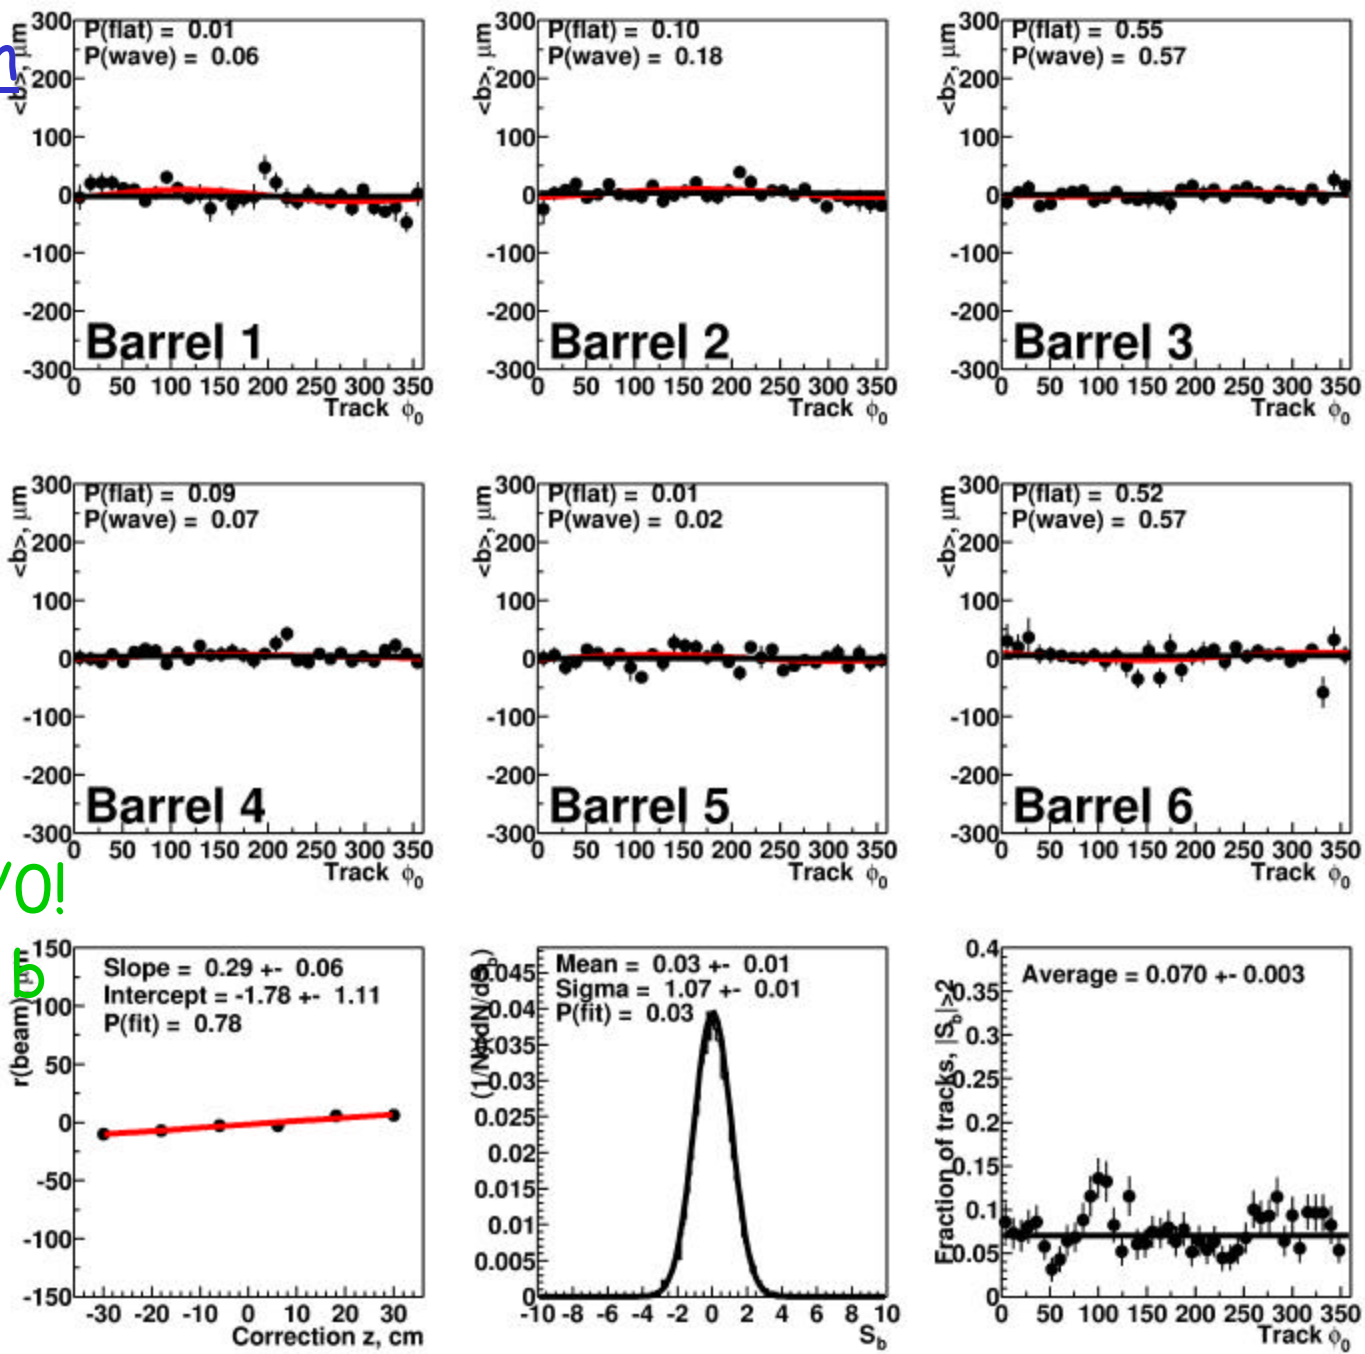

Tilt sample, again

after applying  
barrel+layer  
correction

expect  
 $m_r = 0 \text{ mm/cm}$   
 $\phi = \text{random}$

find,  
 $m$  consistent w/0!  
Slightly better fit

## Conclusions

- either correction method alone beats none
- negligible differences between the two methods
  - similar fit probabilities for flatness
  - identical impact parameter widths
- barrel-only slightly better
  - slightly less physics dependence
  - simpler

So stick with barrel only correction...
